INTRODUCTION TO NETWORKX

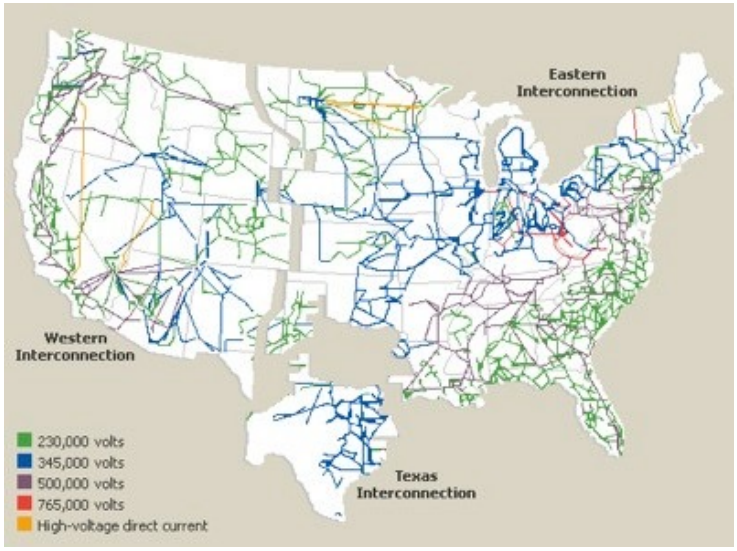
Introduction to NetworkX - network analysis

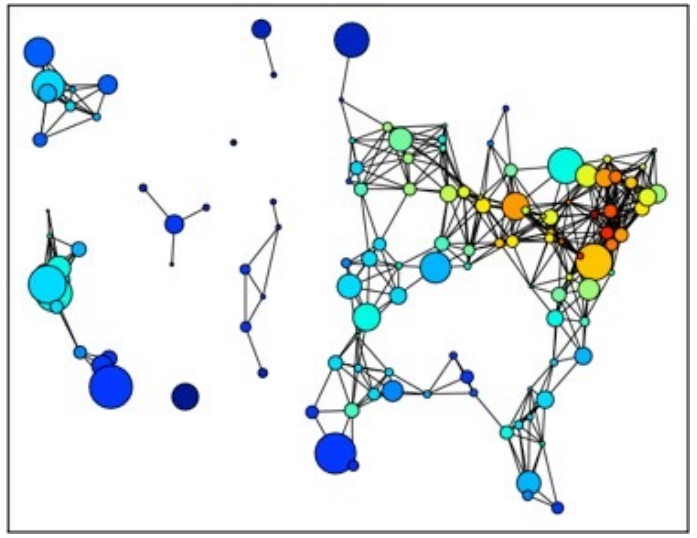
- Vast amounts of network data are being generated and collected
- Sociology: web pages, mobile phones, social networks
- Technology: Internet routers, vehicular flows, power grids

NetworkX è una libreria Python che permette di lavorare con i grafi!

How can we analyse these networks?

Python + NetworkX!



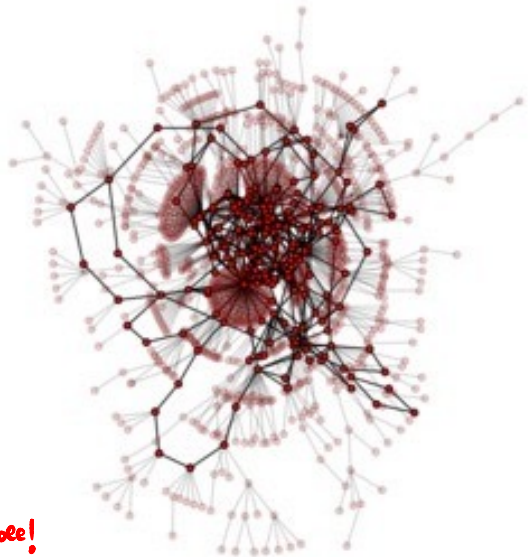


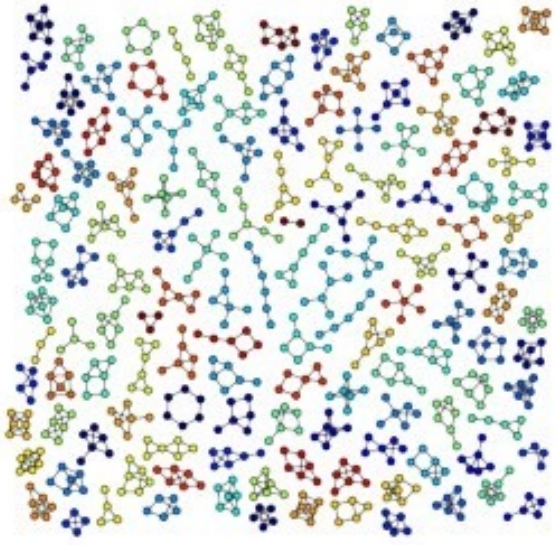
Introduction to NetworkX

“Python package for the creation, manipulation and study of the structure, dynamics and functions of complex networks.”

- Data structures for representing many types of data in the form of graphs
- Nodes can be any (hashable) Python object, edges can contain arbitrary data
- Flexibility ideal for representing networks found in many different fields
- Easy to install on multiple platforms
- Online up-to-date documentation
- First public release in April 2005

nodi sono rappresentati da oggetti che devono essere hashabee!





Introduction to NetworkX - design requirements

- Tool to study the structure and dynamics of social, biological, and infrastructure networks
- Ease-of-use and rapid development
- Open-source tool base that can easily grow in a multidisciplinary environment with non-expert users and developers
- An easy interface to existing code bases written in C, C++, and FORTRAN
- To painlessly slurp in relatively large nonstandard data sets

Introduction to NetworkX - object model

NetworkX defines no custom node objects or edge objects

- node-centric view of network
- nodes can be any hashable object, while edges are tuples with optional edge data (stored in dictionary)
- any Python object is allowed as edge data and it is assigned and stored in a Python dictionary (default empty)

- I nodi sono qualsiasi oggetto hashable;
- Gli archi sono tuple con eventuali informazioni aggiuntive salvate in dizionari.

Introduction to NetworkX - quick example

- Search for the shortest path in a weighted and unweighted network:

N.B: I nodi sono UNICI! Non posso aggiungere due volte lo stesso nodo a un grafo.

```
1 import networkx as nx
2 g = nx.Graph()
3 g.add_edge("a","b",weight=1)
4 g.add_edge("b","c",weight=100)
5 g.add_edge("a","c",weight=1)
6 g.add_edge("c","d",weight=1)
7 print(nx.shortest_path(g,"b","d"))
8 print(nx.dijkstra_path(g, "b", "d", weight='weight'))
```

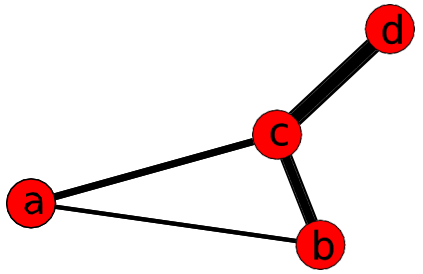
Importo la libreria

Creo un grafo

Creo degli archi; automaticamente vengono aggiunti i nodi se non presenti!

.shortest_path() restituisce il percorso + breve

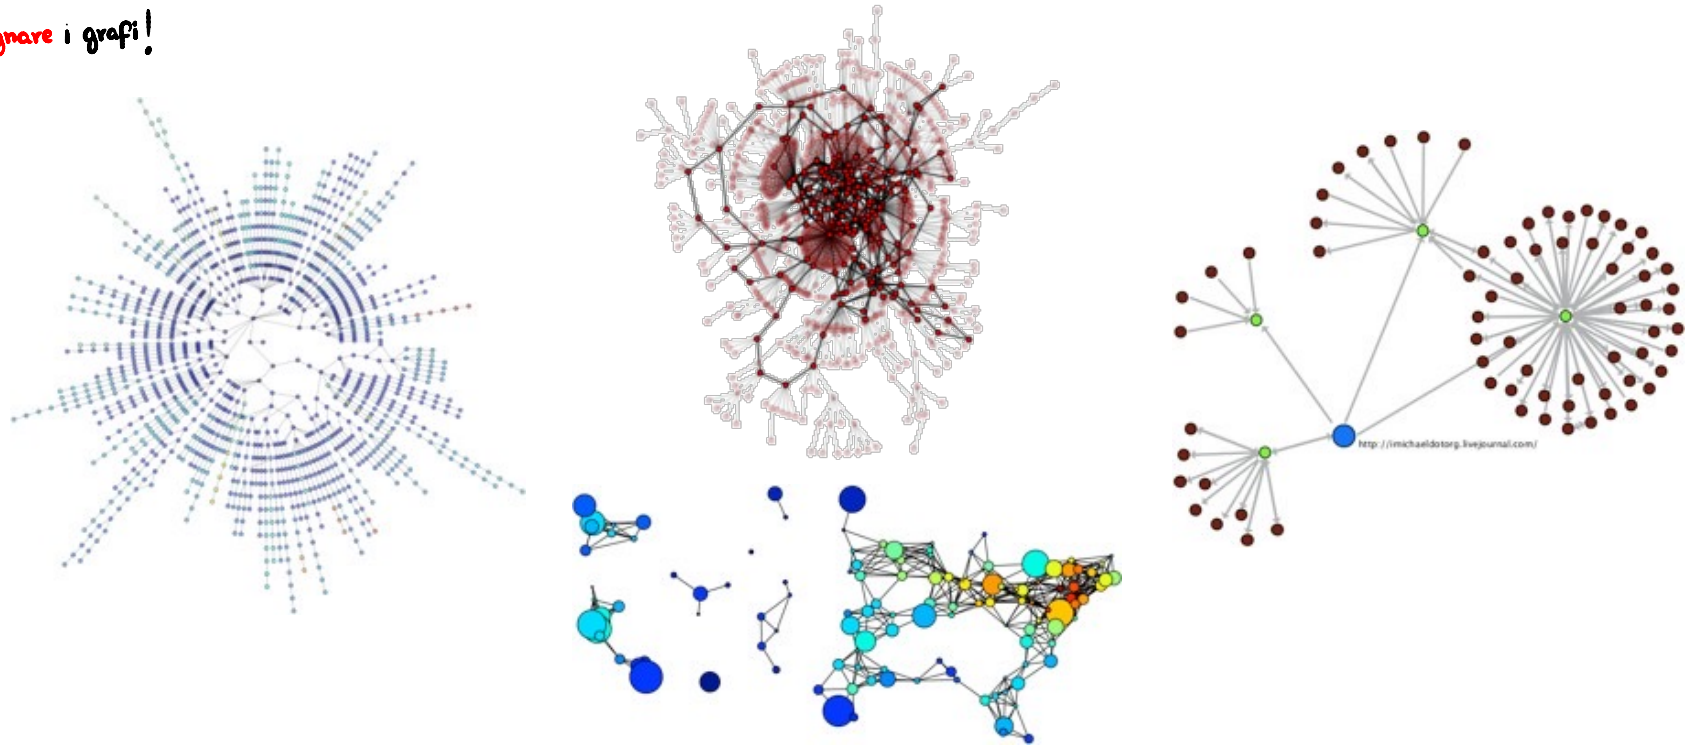
.dijkstra_path(): restituisce il percorso + breve con l'algoritmo di Dijkstra!



Introduction to NetworkX - drawing and plotting

- It is possible to draw small graphs within NetworkX and to export network data and draw with other programs (i.e., GraphViz, matplotlib)

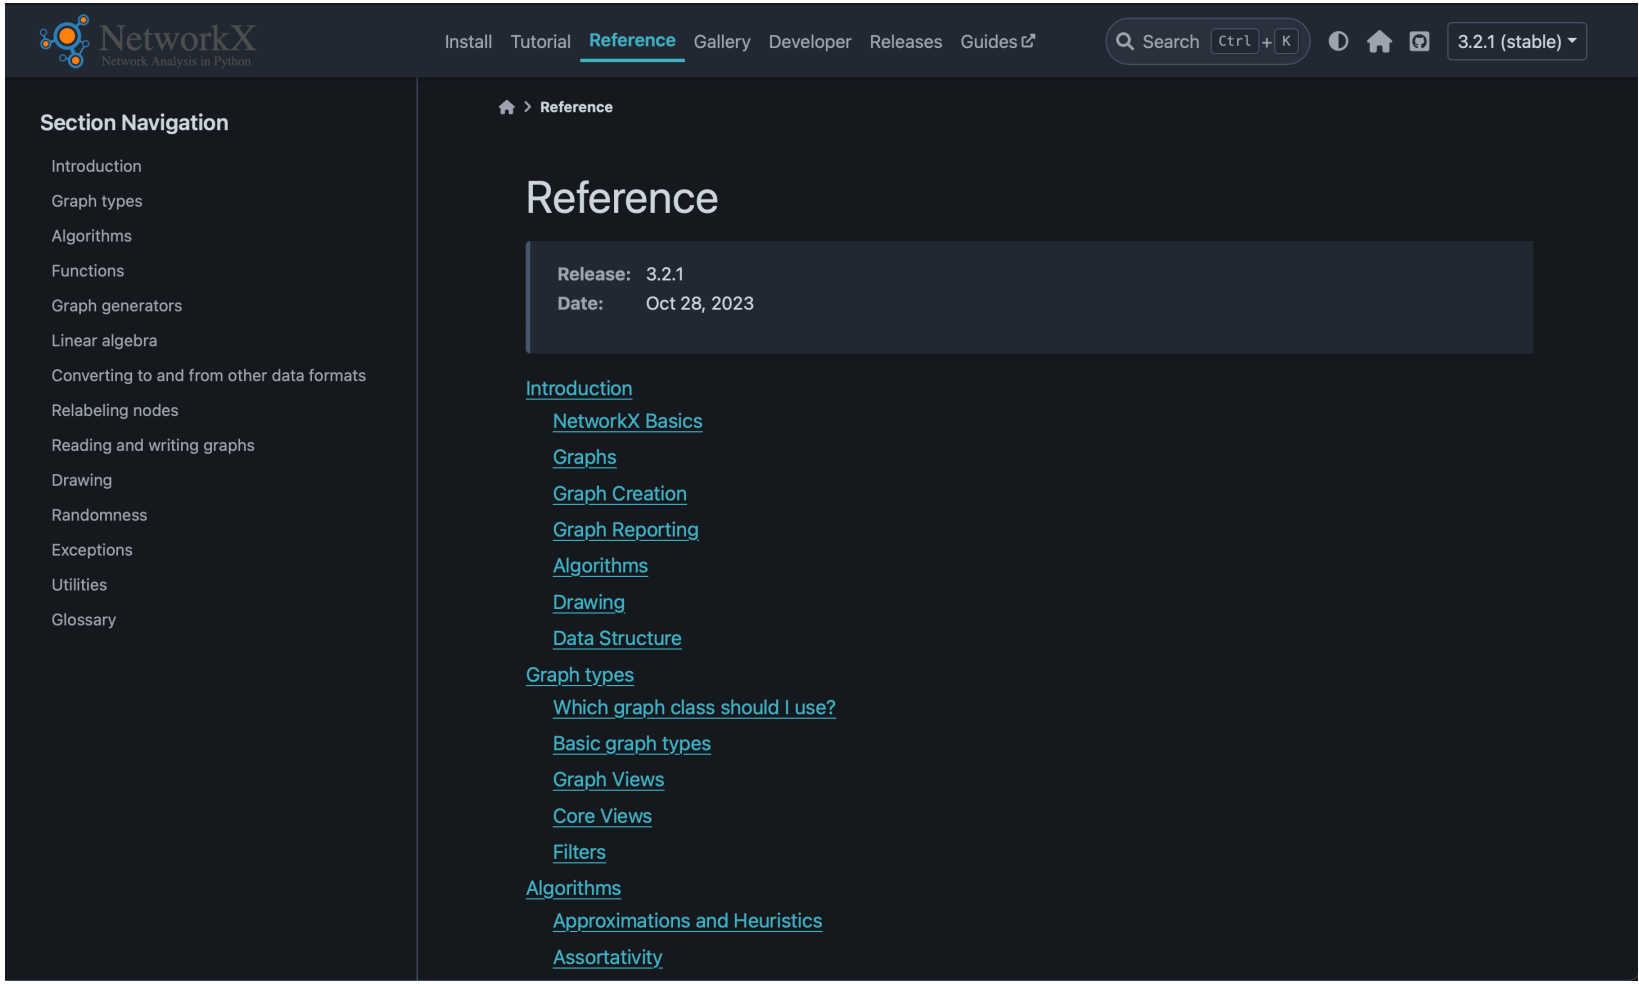
Con NetworkX si possono anche disegnare i grafi!



Introduction to NetworkX - official website

- https://networkx.org/

Documentazione di NetworkX!



GETTING STARTED WITH PYTHON AND NETWORKX

Getting started – import NetworkX

.Graph(): grafo non diretto
.DiGraph(): grafo diretto
.MultiGraph(): multigrafo non diretto
.MultiDiGraph(): multigrafo diretto

- NetworkX supports many different graph types, like:
  - `nx.Graph()` – undirected
  - `nx.DiGraph()` – directed
  - `nx.MultiGrap()` – supports multiple edges between nodes
  - `nx.MultiGrap()` – directed multigraph
- Also provide implementation of notable graphs (like heawood)

Con networkX, a seconda del metodo utilizzato, posso creare grafi di tipo ≠.

```python
import networkx as nx
import math
import flet as ft

g = nx.heawood_graph()
print(g.nodes, g.edges)

g.add_node(math.cos)  # cosine functionx
g.add_node(ft.Text("Pippo"))
g.add_edge("math.cos", 3)
print(g.nodes, g.edges)
```

N.B: I nodi sono UNICI! Non posso aggiungere due volte lo stesso nodo a un grafo.

Getting started – build a graph

- Nodes could be (almost) anything
  - Numbers, strings
  - Objects
  - Functions
  - Flet containers

I nodi possono essere oggetti di qualsiasi tipo!

Gli archi possono anche connettere oggetti di tipo ≠.

- Edges connect nodes (even heterogeneous)
- Nodes and edges could have attributes

↳ Sia i nodi che gli archi possono avere attributi!

```python
import networkx as nx
import math
import flet as ft

g = nx.Graph()
g.add_edge(1, 2)  # default edge data=1
g.add_edge(2, 3, weight=0.9)  # specify edge data

g.add_edge('y', 'x', function=math.cos)
g.add_node(math.cos)  # any hashable can be a node

elist = [(1, 2), (2, 3), (1, 4), (4, 2)]
g.add_edges_from(elist)
elist = [('a', 'b', 5.0), ('b', 'c', 3.0), ('a', 'c', 1.0), ('c', 'd', 7.3)]
g.add_weighted_edges_from(elist)
g.add_node(ft.Text("Pippo"))

print(g.nodes())
print(g.edges())
print(g.get_edge_data('a','b'))
```

↳ Se voglio aggiungere archi pesati, dovrò creare delle tuple formate da tre elementi in cui i primi due identificano l'arco, e il terzo identifica il peso associato all'arco!

Getting started – Data Structure

- I grafi in realtà sono dizionari in cui i nodi sono le chiavi e i valori sono tutti i nodi raggiungibili da quel nodo sottoforma di dizionari, in cui le chiavi sono i nodi e i valori sono tutti i nodi raggiungibili da quel nodo sotto forma di dizionari, e così via...

- A graph is essentially a "dictionary of dictionaries of dictionaries"
- The keys are the nodes
- Indeed, `g[n]` yields a dictionary where keys are all the nodes connected with n (adjacency) and values are the edges params (like weight)

- g[n]: mi restituisce tutti i nodi che sono connessi al nodo n!

```python
import networkx as nx

g = nx.Graph()
g.add_edge(1, 2)  # default edge data=1
g.add_edge(2, 3, weight=0.9)  # specify edge data

elist = [(1, 2, 1), (2, 3, 1), (1, 4, 1), (4, 2, 1),
         ('a', 'b', 5.0), ('b', 'c', 3.0), ('a', 'c', 1.0), ('c', 'd', 7.3)]
g.add_weighted_edges_from(elist)

print(g[2])
```

```
{1: {'weight': 1}, 3: {'weight': 1}, 4: {'weight': 1}}

Process finished with exit code 0
```

Getting started – Data Structure

- `g[u][v]` yields the edge attributes
- `n in g` tests if node `n` is in `g`
- `for n in g:` iterates through the graph
- `for nbr in g[n]:` iterates through the neighbors of n
- Data struct for direct graphs is only slightly more complex (two dics, one for successors and one for predecessors)
- You can also use `g.nodes()` and `g.edges()` to get corresponding data
- Edges can have arbitrary attributes

Accedo agli attributi dell'arco che collega il nodo u e il nodo v.

True/False se il nodo n è presente nel grafo.

Itero sui nodi del grafo

Itero sui nodi collegati al nodo n.

g.nodes(): restituisce i nodi del grafo
g.edges(): restituisce gli archi del grafo.

```
import networkx as nx

g = nx.Graph()
g.add_edge(1, 2)  # default edge data=1
g.add_edge(2, 3, weight=0.9)  # specify edge data

elist = [(1, 2, 1), (2, 3, 1), (1, 4, 1), (4, 2, 1),
         ('a', 'b', 5.0), ('b', 'c', 3.0), ('a', 'c', 1.0), ('c', 'd', 7.3)]
g.add_weighted_edges_from(elist)
g.add_edge(2,5,arbitraryAttr = "foo")

print(g[2])
print("---------")
print(g['a']['b'])
print("---------")
print('e' in g)
print("---------")
for n in g:
    print (n)
print("---------")
for nbr in g[2]:
    print(nbr)
print("---------")
print(g[2][5]['arbitraryAttr'])
```

Getting started – Directed and Multi

- Graphs can be directed, therefore differentiating neighbors in predecessors and successors
- Two nodes can have more than one edge

```
import networkx as nx

dg = nx.DiGraph()
dg.add_weighted_edges_from([(1,4,0.5), (3,1,0.75)])

print([s for s in dg.successors(1)])
print([p for p in dg.predecessors(1)])

mg = nx.MultiGraph()

mg.add_weighted_edges_from([(1,2,.5), (1,2,.75),
(2,3,.5)])

print(mg[1][2])
```

- predecessors(n): restituisce una lista con tutti i nodi predecessori di n.
- successors(n): restituisce una lista con tutti i nodi successori di n.

Getting started - graph operators

In breve, mentre il metodo `union()` unisce tutti gli archi e nodi di entrambi i grafi, e il metodo `disjoint_union()` crea un nuovo grafo con nodi distinti, il metodo `compose()` crea un grafo che include solo gli archi che si sovrappongono tra i due grafi originali.

Classic graph operations

- `subgraph(G, nbunch)` - induce subgraph of G on nodes in nbunch
- `union(G1,G2)` - graph union
- `disjoint_union(G1,G2)` - graph union assuming all nodes are different
- `compose(G1,G2)` - combine graphs identifying nodes common to both
- `complement(G)` - graph complement
- `create_empty_copy(G)` - return an empty copy of the same graph class
- `convert_to_undirected(G)` - return an undirected representation of G
- `convert_to_directed(G)` - return a directed representation of G

↳ Questi due metodi servono rispettivamente x ricevere una versione non orientata di un grafo orientato passato in input, o viceversa!

- Accedere agli attributi degli archi:

```
myGraph.edges(data=True)
# In questo modo, con data=True, .edges mi restituisce non solo una lista di tuple formate da due elementi in cui vengono
# indicati i nodi tra cui è presente un arco, ma all'interno delle tuple ci sono tanti altri argomenti quanti sono gli attributi
# di quell'arco sotto forma di dizionari. Quindi se scrivo .add_edge(1,2,weight=10), quando mi prendo gli edges del grafo con data=True,
# oltre ad avere (1,2), avrò (1,2,{'weight':10}).
# Un'altra opzione che posso avere dato i nodi di un arco per ottenere gli attributi associati all'arco, è utilizzare
# il metodo .get_edge_data(), a cui passo come parametri i due nodi e mi restituisce un dizionario con tutti gli attributi
# e i valori associati a quegli attributi dell'arco.
```
